13. ABSTRACT (Maximum 200 words) Swatches from four commercially-available Level A protective suits were challenged with liquid droplets of sarin (GB) and mustard (HD) using modifications of the static diffusion procedure described in TOP 8-2-501. The cumulative mass of each agent that permeated each swatch was determined over time, and the results for all swatches were used to determine a weighted-average cumulative mass for each suit. From these data, a physiologically-derived breakthrough time was calculated for each suit for the purposes of comparison. In addition, intact suits were challenged with corn-oil aerosol to simulate biological and chemical aerosols. Protection factors were determined for each suit.

EXECUTIVE SUMMARY

As part of the Domestic Preparedness Program, four Occupational Safety and Health Administration Level A* suit designs were tested to assess their capability to protect in a chemical warfare (CW) agent or biological agent environment. Swatches of material from each suit design were tested for resistance to permeation by sarin (GB) and mustard (HD). From these data, the authors calculated the estimated time it would take to permeate the suit with sufficient agent to cause physiological effects in a person wearing the suit. Each suit design was also tested for its protection factor in an aerosol environment (aerosolized corn oil, which may be representative of a chemical or biological agent, was used). Protection factor (PF) is defined as the ratio between the challenge concentration outside the suit and the measured concentration inside the suit. The tests are described, and the calculated physiologically-derived breakthrough times and PFs are presented.

* Level A protection consists of a completely encapsulating, gas/vapor proof chemical resistant suit; a self-contained breathing apparatus (SCBA) or positive-pressure supplied-air respirator with escape SCBA, chemical resistant gloves and boots.

TEST RESULTS OF PHASE 3 LEVEL A SUITS TO CHALLENGE BY CHEMICAL AND BIOLOGICAL WARFARE AGENTS AND SIMULANTS: SUMMARY REPORT

1. INTRODUCTION

In 1996, Congress passed Public Law 104-201 (Defense Against Weapons of Mass Destruction Act of 1996), directing the Department of Defense (DoD) to assist other federal, state, and local agencies in enhancing preparedness for terrorist attacks using weapons of mass destruction. The DoD responded by forming the Domestic Preparedness Program that same year. One of the objectives of the Domestic Preparedness Program is to enhance emergency and hazardous material response to nuclear, biological and chemical (NBC) terrorism incidents. As part of an effective response, people who are responding to an incident will use personal protective equipment to protect them from exposure to chemical agents or biological agents. The specific personal protective equipment (PPE) that would be used by emergency responders depends upon the situation that they encounter and the PPE the responders currently possess. This information can be used by these emergency responders to establish work rules for safe work limits for Level A suits they currently possess, and can be used in deciding which Level A suits to purchase in the future. Level A protective suits are required when the greatest level of skin, respiratory, and eye protection is required, or when entering an unknown environment. Air is supplied by a pressure-demand full-facepiece self-contained breathing apparatus (SCBA) or supplied air lines.

2. OBJECTIVES

This study evaluated four different common and commercially available Level A suits. These four different suits met the Occupational Safety and Health Administration (OSHA) description of Level A as defined in 29 Code of Federal Regulations (CFR) 1910.120, Appendix B. These suits were evaluated to assess how well they resist vapor permeation* from liquid contamination by chemical agents Sarin (GB) and mustard (HD) and droplet penetration by a corn-oil aerosol from 0.4 to 0.6 μ in diameter (used to simulate the 0.4 to 5 μ military standard for the possible biological or chemical particulate threat). This information is intended for emergency responders as an aid in evaluating Level A suits when they choose to include military chemical and biological agent protection as a criterion. The information supplements data and information provided by the suits' manufacturers. The suits are tested in new, as-received condition. The effects of aging, temperature extremes, laundering, and other factors are beyond the intended scope of this test program. These tests are conducted to assess percutaneous protection** only.

* Throughout this report the term permeation is used even though for some of the tests the precise mechanism of agent transfer is not determined and penetration is likely to be involved also.

** Inhalation and ocular protection are typically provided by the use of a SCBA or air-supplied respirator that covers the eyes, nose and mouth.

3. TESTING AND DATA ANALYSIS

3.1 Testing Overview.

The Level A suits that are tested in this test program are listed in Table 1.

Table 1. Level A Suits Tested

Model	Manufacturer	Address
Lakeland Deluxe Level A 10640	Lakeland Industries, Inc.	Somerville, AL
Lakeland Economy Level A 10660	Lakeland Industries, Inc.	Somerville, AL
Mar Mac Commander 9400FB	Mar Mac Manufacturing, Inc.	McBee, SC
Giat UNISCAPH Gas Tight Suit	Centech Group, Inc.	Fairfax, VA

Tests include the measurement of vapor permeation of both GB and HD through material swatches. Tests are also conducted to measure the total aerosol leakage into the suits through seams, seals, etc., when worn as part of a complete PPE system.

3.2 Liquid Challenge/Vapor Permeation Testing (Agent Swatch Testing).

3.2.1 Liquid Challenge/Vapor Permeation Testing Procedures.

This testing is conducted to measure the actual permeation of chemical agents GB and HD through suit swatches over a 24-hr period. The test is intended to assess how well the suit materials and seams resist agent permeation. For each suit design, all swatches were taken from a single suit. The amount of agent applied and duration of exposure do not represent any particular threat that responders would possibly encounter, but serve as a common point of reference for all test results.

The test methodology was taken from TOP 8-2-501¹ and is described in Appendix A. Three swatches are taken from each of six different areas of the suit – 18 total swatches per suit design for GB and 18 more for HD. Swatches are also taken from silicone rubber (M45 mask formulation) slabs. For each test, six swatches taken from a suit and one silicone swatch are placed in test cells, one swatch per test cell. Laboratory personnel apply a predetermined liquid agent challenge (10 g/m²) to the top surface of each swatch. Agent droplets are applied to the surface of the first swatch at time zero. Agent is then applied to the surface of each succeeding swatch at 3-min intervals. The upper chamber of each test cell is sealed. A 1.0 L/min airflow, from the test cabinet, is maintained in the lower test cell chamber beneath each swatch.

¹ *Permeation and Penetration of Air-Permeable, Semipermeable and Impermeable Materials with Chemical Agents or Simulants* (Swatch Testing); Test Operations Procedure (TOP) 8-2-501; U.S. Army Dugway Proving Ground: Dugway, UT, UNCLASSIFIED Report (AD-A322329).

During the 24-hr test period, gas samples are taken on a sequential basis by a laboratory MINICAMS™ (OI Analytical, CMS Field Products Group, Birmingham, AL) with stream selection system (a miniaturized gas chromatograph with flame photometric detector and sampling system) from the airstream beneath each swatch. Gas sampling by the MINICAMS™ begins for the first swatch approximately 3 min following agent application. Subsequent 3-min cycles of the MINICAMS™ are composed of 2 min of desorption of collected agent vapor from the pre-concentrator tube (PCT) onto the GC column followed by 1 min of gas sampling (collection of agent vapor from the next swatch by the PCT). Sampling is done sequentially through six swatches (three from one sampling area followed by three from a second sampling area), the silicone swatch,* and then three blank gas samples are taken from the test chamber to purge the sampling line before repeating the sampling sequence. The six swatches, the silicone swatch, and three blanks are all sampled for the first time within the first 30 min of the test. Then the sampling sequence begins anew.

The MINICAMS™ first determines the amount of agent vapor in each gas sample. Using this result, the amount (ng) of agent vapor present in the airstream that passes beneath the swatch over the time from the previous gas sample to the current gas sample is determined by the MINICAMS™ permeation software. This amount of agent vapor is presumed to be the amount of agent vapor that has permeated the swatch over that time interval. Given the area of the test swatch, the MINICAMS™ permeation software determines the M_f at each elapsed time for each swatch, where the cumulative mass of agent permeating the swatch per unit area at any elapsed time during the 24-hr test is defined as M_f .

3.2.2 Liquid Challenge/Vapor Penetration Testing Analysis.

Each suit yielded M_f data for 18 swatches for each of the two agents. For this report, the average (of three swatches) cumulative permeation (M_f) for each suit area (for example gloves) is calculated. This average is then presented, at each of the reported elapsed times, as representative of the suit's permeation resistance at that sampling area. The reported elapsed time for each sampling area is the sum of the elapsed times for the three swatches divided by three.

To estimate M_f at each elapsed time for a suit, the simplifying assumption is that the exposure is uniform over the entire suit. This permits the use of the weighting factor scheme developed by Belmonte² to determine the weighted average M_f over the entire suit at each average elapsed time. The average elapsed time is the sum of the reported elapsed times for all the sampling areas divided by the number of sampling areas. The weighting factors shown in Table 2 were assigned roughly on the basis of surface area assigning a minimum assigned value of 5%. Swatches were not necessarily taken from exactly the same locations for all suits because

* Originally, it was intended to use silicone swatches as references or controls, but it was soon found that permeation through the silicone varies too widely for it to be used for that purpose. Silicone swatches were used anyway, because they serve as a reliable source of agent vapor to assure the tester that the MINICAMS™ is responding properly during tests when little or no agent permeates the actual test swatches.

² Belmonte, R.B., *Test Results of Level A Suits to Challenge by Chemical and Biological Warfare Agents and Simulants: Summary Report; ERDEC-TR-513*; U.S. Army Edgewood Research, Development and Engineering Center: Aberdeen Proving Ground, MD, 1998; UNCLASSIFIED Report (AD-A353013).

their configurations differed. Note that not all suits have the same components. The weighted average M_f at any average elapsed time is calculated using an equation similar to the following (using the Lakeland Deluxe suit weighting factors in Table 2 for this example):

Weighted average $M_f = 0.5(\text{suit material } M_f) + 0.15(\text{suit seam } M_f) + 0.15(\text{visor material } M_f) + 0.1(\text{glove material } M_f) + 0.05(\text{boot seam } M_f) + 0.05(\text{zipper/material seam } M_f)$

Table 2. Weighting Factors For Each Sampling Area by Suit

Suit Model	Suit Material	Suit Seam	Visor Material	Glove Material	Hood Seam	Boot Seam	Zipper/Material Seam
Lakeland Deluxe Level A 10640	50	15	15	10	-	5	5
Lakeland Economy Level A 10660	50	15	15	10	-	5	5
Mar Mac Commander 9400FB	50	-	15	10	15	5	5
Giat UNISCAPH Gas Tight Suit	50	15	15	10	-	5	5

3.2.3 Relationship Between Liquid Challenge/Vapor Permeation Test Results and Skin Exposure.

The permeation test is designed to distinguish among these material swatches according to their permeation resistance to chemical agents. It is not intended to specifically replicate threat scenarios that may be encountered in actual use. As previously reported by Belmonte,² it is instructive to estimate the agent dosage ($C_{it,skin}$) that would result from such a standard agent challenge as a relative indication of possible physiological effects. This is done by converting the weighted average M_f s to equivalent agent dosages. This relationship was developed by Fedele (written communication, Dr. P. Fedele, R&T Directorate, ERDEC, July 1997) and was reported by Belmonte.² For suit materials impermeable to airflow, the equation is:

$$\text{Agent Dosage (mg - min/m}^3\text{)} = \frac{M_f \text{ (ng/cm}^2\text{)}}{P_s, \text{ Permeability of skin to agent vapor (cm/min)}}$$

where skin permeability (P_s) is 2 cm/min for HD and 0.1 cm/min for GB. The agent dosage can then be compared to doses that are known to cause certain levels of toxicity. Skin permeability is assumed to be constant over all regions of the body.

² Belmonte, R.B., *Test Results of Level A Suits to Challenge by Chemical and Biological Warfare Agents and Simulants: Summary Report; ERDEC-TR-513*; U.S. Army Edgewood Research, Development and Engineering Center: Aberdeen Proving Ground, MD, 1998; UNCLASSIFIED Report (AD-A353013).

3.2.4 Evaluation Criteria for Liquid Challenge/Vapor Permeation Test Results.

When analyzing the test results, it is useful to determine whether the data indicate that the Level A suit provides percutaneous protection over some period of time. Mustard vapor can produce erythema (reddening of the skin, certain body regions) at dosages of approximately 100 mg-min/m^3 , and can produce vesication (skin burns and blisters, certain body regions) at 200 mg-min/m^3 .

Sarin vapor can produce incapacitation (twitching, convulsions or loss of consciousness) at unprotected, percutaneous, whole-body dosages of approximately 8000 mg-min/m^3 and can be lethal at unprotected, percutaneous dosages of 15000 mg-min/m^3 where exposed persons are healthy, young, fit, and well-nourished males of approximately 70-kg mass. People who are smaller, less fit, etc., may exhibit adverse effects at lower doses ($C_{i\text{-skin}}$). The conservative simplifying assumptions were that the suit would be exposed to a uniform liquid GB challenge over its entire surface, and that this would result in a uniform exposure of all body regions to GB vapor. This is conservative because the areas likely to receive more exposure (hands, arms, chest, back) would also be those less sensitive. Therefore, the amount of agent per unit area (weighted average M_f) necessary to permeate the suit to produce a predetermined physiological effect was estimated by using each of the above dosages and the appropriate skin permeability (P_s). These values are used in the graphs of weighted average M_f versus time given in Appendixes C through G and summarized in Table 3. The breakthrough dosages are assumed to be the HD dosage that produces erythema (100 mg-min/m^3) and the GB dosage that produces incapacitation (8000 mg-min/m^3). A physiologically-derived breakthrough time is the time when the weighted average M_f equals the breakthrough dosage criterion.

Table 3. Agent Breakthrough Criteria

Agent	Breakthrough Dosage (mg-min/m^3) ^a	Physiological Effect	Skin Permeability (P_s), (cm/min)	Breakthrough M_f , (ng/cm^2) ^a
HD	100	Erythema	2	200
HD	200	Vesication	2	400
GB	8000	Incapacitation	0.1	800
GB	15000	Lethality	0.1	1500

^a These breakthrough criteria are not to be construed as safe threshold values, they are being used only to rank suits.

3.3 Aerosol Simulant Tests.

3.3.1 Test Procedures.

The testing is conducted to determine leakage of a challenge corn-oil aerosol (physical simulant of a biological or chemical agent aerosol) into a suit ensemble while people of different sizes are wearing appropriately sized ensembles. Volunteers dressed in Level A suits with SCBA enter a chamber with aerosol simulant and remain for 40 min. Instrumentation measures any aerosol leakage (penetration) into the suit through gaps between ensemble

components (vapor permeation through materials cannot be measured by this technique). During the test, the people in the suits perform standardized movements. A brief description of the test and movements made by the people during the test are given in Appendix B. Four different ensembles, listed in Table 1, were tested. Eight suits of each design were worn by 12 volunteers on each of two days, for a total of 24 trials for each suit design. However, because it was not possible to retain the same 12 volunteers throughout the entire course of testing, this variable (the differences among wearers) was not held constant across all suit designs.

From this test a protection factor (PF) is derived. In simplest terms, PF is a measure of the challenge concentration outside the suit divided by the concentration inside the suit ensemble. For example, if the concentration of aerosol inside the suit ensemble is found to be 1/10th the value of the average concentration outside the suit ensemble, the PF is equal to 10.

3.3.2 Aerosol Simulant Analysis.

Samples of aerosol are taken continuously at the visor and upper arm within the suit and their concentrations are measured by laser photometry, recorded in a computer file and displayed continuously on a computer monitor. These sampling locations were selected as being the most likely locations for aerosol leakage to occur because suits tend to leak through outlet valves and zippers. So this is thought to be worst case and the PF is a worst case PF.

The PF data are presented based upon predetermined PF pass levels, ranging from 2 to 100,000 (i.e., at each pass level the number of failing and passing suits is recorded). The higher the percentage of test occasions that passes at a given PF, the greater the probability that the suit will provide that level of protection in use.

The exercises can reveal weaknesses in suit designs. Heavy work can affect the performance of a suit. For example, outlet valves could begin leaking due to moisture escaping from the suit.

APPENDIX A

MODIFIED STATIC DIFFUSION TEST PROCEDURE

MODIFIED STATIC DIFFUSION TEST

This test procedure was adapted from Test Operations Procedure (TOP) 8-2-501, Permeation and Penetration of Air-Permeable, Semipermeable and Impermeable Materials with Chemical Agents or Simulants (Swatch Testing). U.S. Army Dugway Proving Ground, UT, 3 March 1997, UNCLASSIFIED Report (AD A322329). The test procedure was entitled "Semipermeable and Impermeable Materials Static Diffusion Penetration Testing (Liquid Agent Challenge/Vapor Penetration; $\Delta p = 0$, Single Flow Test)". The following procedure was used:

1. Upon receipt of a suit, all available information concerning the suit will be recorded; date of manufacture, lot number, serial number, materials of construction, etc.
2. From each suit, three each 1 and 15/16-in diameter material swatches will be taken for mustard (HD) and a like number taken for sarin (GB). Depending upon the suit configuration, 3 seam swatches (same diameter) will be taken plus 3 swatches of other flat components such as visor, gloves, suit/visor interface and zipper/material interface for HD and an equal number for GB. Each swatch will be placed in an airtight bag and given a unique serial number, which will be placed on the bag. A list of serial numbers will be kept with the swatches. Alternatively, the swatches for each day's test will be cut from the suit and placed in the environmental chamber for conditioning. Sample identification will accompany each swatch.
3. The environmental chamber will be controlled at a temperature of 90 ± 2 °F, and the maximum achievable relative humidity (RH) without occurrence of condensation (normally $50\% \pm 10\%$ RH). The temperature and RH readings will be checked weekly with a calibrated meter. The test cell air will be drawn from the chamber air. The TOP 8-2-501 specifies that a system control and data acquisition system will be used, but this system will not be used due to budget constraints. The temperature and RH will be recorded in a computer file. Flow rates will be manually recorded. The TOP 8-2-501 specifies that differential pressure monitoring will be done but differential pressure gages will not be used due to budget constraints.
4. The TOP test cell will be used. When assembling, the cell lugs will be tightened by hand to finger tight. The flow rate beneath each swatch will be 1 L/min, which will be controlled by a linear mass flow controller. The flows will be checked with a calibrated test meter weekly. Each test cell will be checked for leaks after assembly by connecting it to the vacuum source and checking that the inlet flow is the same as the outlet flow on the mass flow controller. If the flows don't match, the test cell will be disassembled, adjustments made, the test cell reassembled and flows rechecked.

5. The TOP 8-2-501 specifies that positive control and negative control swatches will be used, but they will not be used due to budgetary and schedule limitations. The swatches will be preconditioned for at least 2 hr and will be monitored by MINICAMS™ for at least one cycle prior to agent application. Eighty-mil silicone will be used, one for each test (six suit swatches and one silicone swatch).

6. Agents GB and HD will be used. The contamination density will be 10 g/m² (8 each 1 µL HD droplets or 10 each 1 µL GB droplets). A robotic agent application system is not available. The agent will be applied using the click/touch method with a repeating dispenser.

7. Seven swatches will be tested at once. MINICAMS™ with stream selection system will monitor vapor penetration with a 3-min cycle. There will be three sampling intervals following the silicone during which chamber air will be sampled. Each swatch will be sampled once every 30 min. The MINICAMS™ will be standardized weekly with a range of agent standards (diluted in isopropanol). Concentrations will normally range from 1 ng/µL to 100 ng/µL.

8. The test length will be 24 hr.

9. The test cells will be aerated and o-rings replaced between uses. No other cleaning method will be used.

10. The data to be reported are cumulative permeation (ng/cm²) at various elapsed times (minutes) for each swatch. The elapsed time for each swatch is the time from agent contamination. All recorded data will be placed in laboratory notebooks and one technical report per suit will be drafted at the conclusion of this effort.

APPENDIX B

AEROSOL SIMULANT TEST PROCEDURE

To properly test suits with statistical significance, eight suit ensembles of each model are provided to the Mask Fit Test Facility for examination. Each ensemble is new and inspected as received. The suit ensembles include relevant accessory equipment such respirators that are worn with the suits, gloves, boots, and any other equipment that is necessary for chemical agent use. The suit ensembles are run on at least 10 different subjects with at least 22 trials. The eight suits are reused to achieve the 22 or more trials. Sampling of suits is done at the visor and upper arm for each trial.

Exercise routine for all suits is as follows:

Phase 1 (Pre-Operational):

- 1) standing still, normal breathing
- 2) bending forward and touching toes
- 3) jogging in place
- 4) raising arms above head and looking upward
- 5) bending knees and squatting
- 6) crawling on hands and knees
- 7) torso twists with hands folded on chest
- 8) standing still, normal breathing

Phase 2 (Operational):

- 1) climb step ladder
- 2) move 3 lb boxes from table to floor
- 3) rest
- 4) roll walls and ceiling
- 5) bag clothes
- 6) rest
- 7) loosen bolts
- 8) move 3 lb boxes from floor to table

Note: The phase 1 (pre-operational) exercises are performed for 1 min each for a total of 8 min. The phase 2 (operational) exercises are performed for 4 min each for a total of 32 min. Hence, the overall total exercise time is 40 min.

Blank

Note 1: The time given for each sampling area is the average of the elapsed times for the three swatches tested per sampling area.

Note 2: The average time is the sum of the times given for each sampling area divided by the number of sampling areas.

Note 3: Weighted average $M_r = 0.5(\text{Suit Matl } M_r) + 0.15(\text{Suit Seam } M_r) + 0.15(\text{Visor Matl } M_r) + 0.1(\text{Glove } M_r) + 0.05(\text{Boot Seam } M_r) + 0.05(\text{Zipper Seam } M_r)$.

Note 1: The time given for each sampling area is the average of the elapsed times for the three swatches tested per sampling area.

Note 2: The avg. time is the sum of the times given for each sampling area divided by the number of sampling areas.

Note 3: Weighted average $M_t = 0.5(\text{Suit Leg Matl } M_t) + 0.15(\text{Suit Arm Seam } M_t) + 0.15(\text{Visor Matl } M_t) + 0.1(\text{Glove Material } M_t) + 0.05(\text{Boot Seam } M_t) + 0.05(\text{Zipper Seam } M_t)$.

Note 1: The time given for each sampling area is the average of the elapsed times for the three swatches tested per sampling area.

Note 2: The avg. time is the sum of the times given for each sampling area divided by the number of sampling areas.

Note 3: Weighted average $M_t = 0.5(\text{Suit Matl } M_t) + 0.15(\text{Hood Seam } M_t) + 0.15(\text{Visor Matl } M_t) + 0.1(\text{Glove Matl } M_t) + 0.05(\text{Boot Seam } M_t) + 0.05(\text{Zipper Seam } M_t)$.

Note 4: Sampling for zipper seam was ended prematurely due to equipment failure.

Note 1: The time given for each sampling area is the average of the elapsed times for the three swatches tested per sampling area.

Note 2: The avg. time is the sum of the times given for each sampling area divided by the number of sampling areas.

Note 3: Weighted average $M_f = 0.5(\text{Suit Matl } M_f) + 0.15(\text{Suit Seam } M_f) + 0.15(\text{Visor Matl } M_f) + 0.1(\text{Glove Matl } M_f) + 0.05(\text{Boot Seam } M_f) + 0.05(\text{Zipper Seam } M_f)$.

Table F - 2. Giat UNISCAPH – Average GB Permeation
